PHARMACOGNOSY AND PHYTOCHEMISTRY - II

UNIT 4

TOPIC :

- Industrial production, estimation and utilization of the following phytoconstituents : Forskolin, Sennoside, Artemisinin, Diosgenin, Digoxin, Atropine, Podophyllotoxin, Caffeine, Taxol, Vincristine and Vinblastine

Forskolin

- Forskolin is a diterpenoid compound obtained from the roots of *Coleus forskohlii* (also known as *Plectranthus barbatus*), belonging to the family Lamiaceae (Labiatae).
- It is one of the most important labdane-type diterpenes, known for its unique ability to activate adenylate cyclase enzyme, which increases the intracellular level of cyclic AMP (cAMP).
- Due to this mechanism, Forskolin exhibits several therapeutic and pharmacological effects, making it useful in pharmaceutical and research industries.

Source

- Biological Source: *Coleus forskohlii* (Roots)
- Family: Lamiaceae
- Active Constituent: Forskolin
- Chemical Nature: Diterpenoid (Labdane-type)
- Molecular Formula: $C_{22}H_{34}O_7$
- Molecular Weight: 410.50 g/mol

Industrial Production of Forskolin

The production of forskolin on an industrial scale involves several stages — from plant cultivation to extraction, isolation, and purification.

A. Plant Cultivation

1. Plant Material:
 - *Coleus forskohlii* is propagated through stem cuttings or tissue culture.
 - It grows well in tropical and subtropical climates with well-drained sandy soil.
2. Harvesting:
 - Roots are harvested after 10–12 months when forskolin content is maximum.
 - The dried roots contain about 0.1–0.3% forskolin.

B. Extraction Process

1. **Drying and Powdering:**
 - Collected roots are cleaned, shade-dried, and ground into coarse powder.
2. **Solvent Extraction:**
 - The powdered roots are extracted using ethanol or methanol in a Soxhlet apparatus or industrial extractor.
 - Extraction is continued for several hours to ensure complete removal of diterpenoids.
3. **Concentration:**
 - The extract is filtered and concentrated under reduced pressure using a rotary evaporator.
4. **Fractionation:**
 - The concentrated extract is dissolved in chloroform or ethyl acetate, then washed with water to remove impurities.
 - The organic layer is separated and evaporated.
5. **Purification:**
 - Purified by column chromatography using silica gel as stationary phase and chloroform:methanol (9:1) as the mobile phase.
 - Fractions containing forskolin are identified by TLC and pooled together.
6. **Crystallization:**
 - Pure forskolin is obtained as colorless crystalline compound by recrystallization from acetone or ethanol.

Estimation of Forskolin

→ Estimation or quantitative determination is carried out to ensure quality control and standardization of forskolin-containing preparations.

A. TLC (*Thin Layer Chromatography*)

- Stationary phase: Silica gel G
- Mobile phase: Toluene : Ethyl acetate : Formic acid (7:3:0.5)
- Detection: Under UV light at 366 nm or by spraying with vanillin-sulfuric acid reagent (violet spot).
- R_f value: 0.45 (approx.)

B. UV-Visible Spectrophotometric Method

1. Prepare ethanolic solution of forskolin.
2. Measure absorbance at $\lambda_{\text{max}} = 320 \text{ nm}$.
3. Calculate concentration using Beer-Lambert's law.
4. This method is simple, economical, and suitable for preliminary estimation.

C. HPLC Method (*High Performance Liquid Chromatography*)

- Column: C₁₈ reverse-phase
- Mobile Phase: Acetonitrile : Water (70:30)
- Flow Rate: 1.0 mL/min
- Detection Wavelength: 220 nm
- Retention Time: 6–8 minutes (depends on system)
- Application: Quantitative determination in plant extracts and formulations.

D. HPTLC Method

- Mobile Phase: Toluene : Ethyl acetate : Formic acid (6:4:0.2)
- Detection Wavelength: 254 nm
- Purpose: Used for simultaneous estimation of forskolin and other diterpenoids in *Coleus forskohlii* extracts.

Utilization of Forskolin

→ Forskolin has multiple pharmacological, therapeutic, and industrial applications due to its unique mechanism of increasing cyclic AMP (cAMP) levels in cells.

A. Pharmacological Uses

1. Antihypertensive:
 - Relaxes smooth muscles in blood vessels and lowers blood pressure.
2. Antiglaucoma:
 - Reduces intraocular pressure; used in ophthalmic preparations.
3. Antiasthmatic:
 - Relaxes bronchial smooth muscle by increasing cAMP levels.
4. Cardiogenic:
 - Increases contractility of cardiac muscle and improves heart function.
5. Weight Management:
 - Enhances lipolysis (breakdown of fat) by activating hormone-sensitive lipase.
6. Antiplatelet and Vasodilator:
 - Inhibits platelet aggregation and improves blood circulation.
7. Anticancer and Anti-inflammatory:
 - Modulates signaling pathways involved in inflammation and cell proliferation.

B. Industrial and Research Applications

- Used as a biochemical tool for studying cAMP-mediated cell signaling.
- Incorporated in herbal formulations and dietary supplements for obesity and heart health.
- Utilized in cosmetic industries for skin toning and metabolic enhancement products.
- Being explored in biotechnological research for tissue culture enhancement and cell metabolism studies.

Sennosides

- Sennosides are anthraquinone glycosides obtained mainly from the leaves and pods of *Cassia angustifolia* (Indian Senna) and *Cassia acutifolia* (Alexandrian Senna).
- They are natural stimulant laxatives, widely used in pharmaceutical preparations to relieve constipation.
- The most active constituents are Sennoside A and Sennoside B.
- These compounds act on the large intestine to stimulate peristaltic movement and promote bowel evacuation.

Source and Chemical Nature

Feature	Description
Biological Source	Dried leaves and pods of <i>Cassia angustifolia</i> and <i>Cassia acutifolia</i>
Family	Fabaceae (Leguminosae)
Active Principles	Sennoside A, B (main); C, D (minor)
Chemical Nature	Anthraquinone glycosides (Dianthrone type)
Molecular Formula (Sennoside A)	$C_{42}H_{38}O_{20}$
Molecular Weight	862.74 g/mol

Industrial Production of Sennosides

→ The industrial production of sennosides involves several stages — from cultivation of Senna plants to extraction and purification of active glycosides.

A. Plant Cultivation

1. Plant Source:
 - *Cassia angustifolia* (Indian Senna) is cultivated in tropical and subtropical regions, mainly in India, Egypt, and Sudan.
2. Cultivation Conditions:
 - Requires warm climate, sandy loam soil, and good drainage.

- Propagated by seeds.
- 3. Harvesting:
 - Leaves are harvested 4–6 months after planting.
 - Pods are collected when mature and dried in shade.
 - Dried material contains about 2–3% sennosides.

B. Extraction Process

1. Drying and Powdering:
 - Dried leaves/pods are powdered to increase surface area.
2. Extraction:
 - The powdered drug is extracted with hot water, ethanol, or hydroalcoholic solvents (70% ethanol).
 - Industrially, percolation or Soxhlet extraction is used for efficiency.
3. Filtration and Concentration:
 - The extract is filtered and concentrated under reduced pressure to form a syrupy mass.
4. Precipitation of Impurities:
 - The concentrate is treated with lead acetate or activated charcoal to remove unwanted pigments and impurities.
5. Isolation of Sennosides:
 - The purified extract is adjusted to acidic pH and extracted with n-butanol or ethyl acetate.
 - The organic layer is separated and evaporated to obtain crude sennosides.
6. Purification:
 - Crude product is recrystallized from ethanol or methanol to yield pure Sennoside A and B.

Estimation of Sennosides

→ Estimation is important for standardization, quality control, and dose determination in pharmaceutical formulations.

A. Chemical Tests

1. Bornträger's Test:

- The sample is hydrolyzed with dilute HCl, extracted with benzene, and shaken with ammonia.
- A pink to red color appears, indicating anthraquinone derivatives.

2. Modified Bornträger's Test:

- Performed for C-glycosides (like sennosides) using ferric chloride and hydrochloric acid before extraction.
- Produces rose-red color in the ammoniacal layer.

B. TLC Identification

Parameter	Description
Stationary Phase	Silica gel G
Mobile Phase	Ethyl acetate : Methanol : Water (100:17:13)
Detection	Under UV light at 254 nm or spraying with 10% KOH (pink-orange spot)
R _f Value	0.5–0.6 (for Sennoside A)

C. UV-Visible Spectrophotometric Estimation

1. Extract Sennosides in aqueous methanol.
2. Measure absorbance at $\lambda_{\text{max}} = 270\text{--}275\text{ nm}$.
3. Apply Beer–Lambert's law for concentration determination.
4. Used for routine analysis in herbal standardization labs.

D. HPLC Method

- Column: C₁₈ reverse-phase
- Mobile Phase: Acetonitrile : 0.1% Orthophosphoric acid in water (30:70)
- Flow Rate: 1 mL/min
- Detection: UV at 270 nm
- Retention Time: ~6–10 min (depending on system)

Utilization of Sennosides

A. Medicinal Uses

1. Stimulant Laxative:
 - Acts on the large intestine to stimulate peristalsis and promote defecation.
 - Used in constipation and bowel preparation before surgery.
2. Treatment of Piles and Anal Fissures:
 - Helps in softening stools and reducing strain during defecation.
3. Detoxification Therapies:
 - Used in Ayurvedic formulations for body cleansing and detox.
4. Pharmaceutical Preparations:
 - Available as Senokot[®], Ex-Lax[®], Cremaffin Plus, etc.
 - Formulated as tablets, granules, syrups, and teas.

B. Industrial and Research Uses

- Used in standardization of herbal drugs containing anthraquinone glycosides.
- Employed as a marker compound in quality control of Senna extracts.
- Studied for its structure–activity relationship (SAR) in drug design.
- Used in the formulation of laxative and detox products in the herbal and nutraceutical industries.

Artemisinin

- Artemisinin is a sesquiterpene lactone endoperoxide compound obtained from the plant *Artemisia annua* (family: Asteraceae).
- It is one of the most important antimalarial phytoconstituents, especially effective against *Plasmodium falciparum*, including chloroquine-resistant strains.
- Due to its potent activity and limited natural availability, large-scale industrial production and semi-synthetic routes have been developed.

Source

- Botanical Source: *Artemisia annua* L. (Sweet wormwood)
- Family: Asteraceae
- Plant Part Used: Leaves and flowering tops
- Active Constituent: Artemisinin ($C_{15}H_{22}O_5$)

Industrial Production

A. Cultivation of Source Plant

- *Artemisia annua* is cultivated in tropical and subtropical regions such as China, India, Vietnam, and Africa.
- Requires warm climate and well-drained soil.
- The plant is harvested at the pre-flowering stage when artemisinin content is maximum.

B. Extraction Process

1. Drying and Powdering:
 - The aerial parts are shade-dried and powdered.
2. Solvent Extraction:
 - Extracted using non-polar solvents like hexane, petroleum ether, or dichloromethane.
3. Concentration:
 - Solvent is evaporated under reduced pressure to obtain a crude extract.
4. Purification:

- Crude extract is purified by column chromatography or recrystallization to isolate pure artemisinin crystals.

C. Semi-Synthetic Production

- Due to limited natural yields (0.01–1%), biotechnological production is used:
 - Microbial fermentation using genetically engineered *Saccharomyces cerevisiae* (yeast) produces artemisinic acid, which is chemically converted to artemisinin.
 - This method is cost-effective and sustainable for large-scale production.

Estimation of Artemisinin

A. Spectrophotometric Method

- Principle: Measurement of UV absorbance at 260 nm after derivatization.
- Reagent Used: Sodium hydroxide or acidic solution for derivatization.
- Application: Useful for routine estimation in plant extracts and formulations.

B. High-Performance Liquid Chromatography (HPLC)

- Column: C₁₈ reverse-phase column
- Mobile Phase: Acetonitrile:Water (70:30)
- Detection: UV detector at 210 nm
- Purpose: Quantitative determination of artemisinin and related derivatives with high precision.

C. TLC (Thin Layer Chromatography)

- Stationary Phase: Silica gel G
- Mobile Phase: Toluene:Ethyl acetate (7:3)
- Visualization: Anisaldehyde-sulfuric acid reagent gives blue spots.

Utilization / Applications

1. Antimalarial Agent:
 - Used in Artemisinin-based Combination Therapies (ACTs) such as:
 - Artesunate + Amodiaquine
 - Artemether + Lumefantrine
 - Dihydroartemisinin + Piperaquine
 - Rapidly acts on *Plasmodium falciparum*, killing both blood and gametocyte stages.
2. Antiparasitic and Antiviral Potential:
 - Shows activity against *Toxoplasma gondii*, *Leishmania*, and *Schistosoma*.
 - Also investigated for antiviral effects (including SARS-CoV-2).
3. Anticancer Research:
 - Exhibits cytotoxic effects on cancer cells due to peroxide bridge interaction with intracellular iron.
4. Pharmaceutical Formulations:
 - Available as tablets, injections, and capsules in combination with other drugs to prevent resistance.

Pharmacy
Learn and Educate

Diosgenin

- Diosgenin is a steroidal sapogenin, a naturally occurring compound obtained from certain species of *Dioscorea* (yams).
- It is one of the most important precursors for the industrial synthesis of steroidal drugs such as corticosteroids, oral contraceptives, and sex hormones.
- Diosgenin itself has pharmacological properties like anti-inflammatory, anticancer, and hypocholesterolemic effects.

Source

Particular	Description
Botanical source	<i>Dioscorea</i> species such as <i>Dioscorea deltoidea</i> , <i>D. floribunda</i> , <i>D. composita</i>
Family	Dioscoreaceae
Plant part used	Tubers and rhizomes
Chemical nature	Steroidal sapogenin (Aglycone part of saponin)
Molecular formula	$C_{27}H_{42}O_3$

Industrial Production of Diosgenin

A. Cultivation of Source Plants

- Dioscorea* plants are cultivated in tropical and subtropical regions (India, Mexico, China).
- The plants are propagated by tuber pieces or stem cuttings.
- They require humid climate, loamy soil, and rainfall between 100–150 cm.

B. Harvesting

- Tubers are harvested after 2–3 years when diosgenin content is maximum.
- They are washed, sliced, dried, and powdered before extraction.

C. Extraction and Isolation Process

1. Acid Hydrolysis Method:

- The powdered tubers are soaked in dilute acid (e.g., 2N HCl) and heated.
- This step hydrolyzes saponins into sapogenins (diosgenin) and sugars.

- The hydrolyzed mass is filtered and washed.
- 2. Solvent Extraction:
 - The residue is extracted using organic solvents such as petroleum ether or chloroform.
 - Solvent is evaporated under reduced pressure.
- 3. Purification:
 - The crude diosgenin is purified by recrystallization using solvents like ethanol or acetone.
 - The final product is a white crystalline powder.

D. Biotechnological Production (Alternative Method):

- Modern industrial production may use biotransformation using *Rhizopus* or *Cunninghamella* species.
- These microorganisms can convert plant saponins into diosgenin efficiently.

Estimation of Diosgenin

A. Spectrophotometric Method

- Principle: Diosgenin reacts with acid to produce a chromogen measured spectrophotometrically.
- Procedure:
 - Diosgenin is treated with vanillin and sulfuric acid reagent.
 - The colored complex is measured at 540 nm.
- Application: Simple and widely used for quantification in crude extracts.

B. High Performance Liquid Chromatography (HPLC)

- Column: C₁₈ reverse-phase
- Mobile phase: Methanol : Water (90:10)
- Detection: UV detector at 205–210 nm
- Advantage: High accuracy and reproducibility for standardization.

C. Thin Layer Chromatography (TLC)

- Stationary phase: Silica gel G plates
- Mobile phase: Chloroform : Methanol (9:1)
- Visualization: Anisaldehyde–sulfuric acid reagent gives violet spots confirming diosgenin.

Utilization of Diosgenin

A. Industrial Utilization

1. Precursor for Steroid Drugs:
 - Diosgenin is used as the starting material in the semisynthesis of steroidal hormones:
 - Corticosteroids (Hydrocortisone, Prednisolone)
 - Estrogens and Progestogens (Progesterone, Norethindrone)
 - Androgens (Testosterone derivatives)
 - It serves as a key raw material for the pharmaceutical steroid industry.
2. Oral Contraceptive Production:
 - Diosgenin → Progesterone → Norethindrone → Oral contraceptives.
3. Corticosteroid Manufacture:
 - Used in the production of anti-inflammatory and anti-allergic drugs.

B. Medicinal and Pharmacological Uses

- Shows anti-inflammatory, antioxidant, hypolipidemic, and anticancer effects.
- Also reported to have antidiabetic and immunomodulatory properties.

C. Cosmetic Industry

- Used in the formulation of skin creams and anti-aging products due to its steroidal structure.

Digoxin

- Digoxin is a cardiac glycoside obtained from the leaves of *Digitalis lanata* (commonly known as Woolly Foxglove).
- It is a potent cardiotonic agent used in the treatment of congestive heart failure (CHF) and certain cardiac arrhythmias.
- Digoxin acts by inhibiting Na^+/K^+ -ATPase, increasing intracellular calcium, which enhances cardiac contractility.

Source

Particular	Description
Biological Source	Dried leaves of <i>Digitalis lanata</i> Ehrhart
Family	Scrophulariaceae
Plant Part Used	Leaves
Active Constituent	Digoxin
Chemical Nature	Cardiac glycoside ($\text{C}_{41}\text{H}_{64}\text{O}_{14}$, MW = 780)

Industrial Production of Digoxin

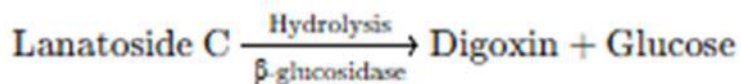

A. Cultivation of the Plant

- *Digitalis lanata* is a biennial or perennial herb, cultivated in temperate climates such as India, Germany, and the U.K.
- The plant requires well-drained soil, moderate rainfall, and partial shade.
- Leaves are harvested before flowering, when glycoside content is highest.
- After harvest, leaves are shade-dried at low temperature to prevent enzyme degradation.

B. Extraction Process

1. Powdering and Defatting:
 - Dried leaves are powdered and defatted with petroleum ether to remove chlorophyll and waxes.
2. Extraction:
 - Extracted with 70% alcohol or methanol under reflux.
 - The extract contains a mixture of cardiac glycosides, including lanatoside A-E.
3. Purification and Conversion:

- Lanatoside C (a major glycoside) is isolated and enzymatically hydrolyzed using β -glucosidase to yield digoxin.
- Reaction:

Digoxin is purified by crystallization from aqueous alcohol.

C. Industrial Scale Production

- Industrial processes use controlled enzymatic hydrolysis of lanatoside C obtained from plant extracts.
- The process includes:
 1. Extraction of total glycosides.
 2. Isolation of lanatoside C by chromatography.
 3. Enzymatic hydrolysis to digoxin.
 4. Crystallization and drying under vacuum.
- Yield: About 0.1–0.2% digoxin from dry leaves.

Estimation of Digoxin

A. Spectrophotometric Method

- Principle: Digoxin forms a colored complex with 3,5-dinitrobenzoic acid or vanillin–sulfuric acid reagent, measurable at 510 nm.
- Use: Preliminary quantitative estimation in extracts or formulations.

B. High Performance Liquid Chromatography (HPLC)

- Column: C₁₈ reverse-phase
- Mobile Phase: Acetonitrile : Water (25:75)
- Flow Rate: 1 mL/min
- Detection: UV detector at 220 nm
- Use: Accurate and precise method for quantifying digoxin in raw materials and dosage forms.

C. Bioassay Method

- Digoxin activity can also be bioassayed using pigeon or frog heart, based on its cardiotonic effect (as per BP/IP methods).

D. Thin Layer Chromatography (TLC)

- Stationary Phase: Silica gel G
- Mobile Phase: Chloroform : Methanol : Water (65:35:10)
- Visualization: Anisaldehyde–sulfuric acid reagent → violet spots

Utilization of Digoxin

1. Congestive Heart Failure (CHF):
 - Increases myocardial contractility (positive inotropic effect).
 - Improves cardiac output and reduces heart size.
2. Atrial Fibrillation and Atrial Flutter:
 - Decreases AV conduction (negative dromotropic effect).
 - Helps control ventricular rate.
3. Atrial Tachycardia:
 - Used for rate control and rhythm stabilization.

Atropine

- Atropine is a tropane alkaloid obtained from plants belonging to the Solanaceae family such as *Atropa belladonna* (Deadly Nightshade), *Datura stramonium*, and *Hyoscyamus niger* (Henbane).
- It is one of the most important anticholinergic (parasympatholytic) drugs used in medicine.
- Chemically, it is an ester of tropine and tropic acid.
- Atropine acts by blocking muscarinic acetylcholine receptors (mAChRs) in smooth muscles, secretory glands, and the central nervous system.

Source

Particular	Description
Biological Source	Leaves and roots of <i>Atropa belladonna</i> L., <i>Datura stramonium</i> , <i>Hyoscyamus niger</i>
Family	Solanaceae
Chemical Nature	Tropane alkaloid
Molecular Formula	$C_{17}H_{23}NO_3$
Chemical Structure	Ester of tropic acid and tropine
Synonym	dl-Hyoscyamine

Industrial Production of Atropine

A. Cultivation of Source Plants

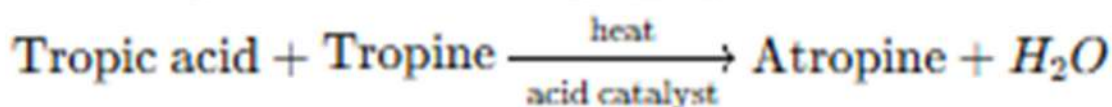

- Plants are cultivated in temperate climates (Europe, India, and North America).
- Require fertile, well-drained soil, and moderate sunlight.
- The roots and leaves are collected when alkaloid content is maximum (usually before flowering).

B. Extraction Process

1. Drying and Powdering:
 - The plant material (leaves/roots) is shade-dried and finely powdered.
2. Extraction of Alkaloids:
 - Powdered material is moistened with alkali (lime or ammonia) to liberate free alkaloids.
 - Extracted with organic solvents like chloroform or ether.
3. Acid-Base Extraction:
 - The organic layer containing alkaloids is treated with dilute sulfuric acid to form soluble alkaloid salts.
 - Then basified again with ammonia, which liberates free atropine.
 - The free base is re-extracted into organic solvent.
4. Purification and Crystallization:
 - Crude atropine is purified by recrystallization from ether or benzene to obtain pure atropine crystals.

C. Industrial or Semi-Synthetic Production

- Industrially, atropine is also prepared semi-synthetically from tropic acid and tropine via esterification reaction:

This method ensures high yield and purity compared to direct extraction.

Estimation of Atropine

A. Chemical (Titrimetric) Method

- Principle: Atropine sulfate is titrated against 0.02 N perchloric acid using methyl red as an indicator in a non-aqueous medium.
- Use: Common in pharmacopeial assays for atropine sulfate injection or tablets.

B. Spectrophotometric Method

- Principle: Atropine reacts with certain reagents (e.g., bromocresol green) forming a colored complex measurable at 415 nm.
- Use: Quantitative estimation in pharmaceutical formulations.

C. High Performance Liquid Chromatography (HPLC)

- Column: C₁₈ reverse-phase column
- Mobile Phase: Methanol : Water : Acetic acid (70:25:5)
- Detection: UV at 215–220 nm
- Advantage: Highly accurate and sensitive method used for quality control.

Utilization of Atropine

1. Anticholinergic Agent:
 - Blocks muscarinic acetylcholine receptors.
 - Reduces salivation, bronchial secretions, and gastric motility.
2. Mydriatic and Cycloplegic:
 - Used in ophthalmology to dilate pupils and paralyze accommodation during eye examination.
3. Preanesthetic Medication:
 - Administered before surgery to reduce salivary and bronchial secretions.
4. Antidote in Organophosphate Poisoning:
 - Used as an antidote to counteract muscarinic effects of organophosphate insecticides and nerve agents.
5. Treatment of Bradycardia:
 - Increases heart rate by blocking vagal effects on the sinoatrial node.
6. Antispasmodic:
 - Relieves spasms in the gastrointestinal and urinary tracts.

Podophyllotoxin

- Podophyllotoxin is a lignan-type secondary metabolite obtained mainly from the roots and rhizomes of Podophyllum species, such as *Podophyllum hexandrum* (Indian Podophyllum) and *Podophyllum peltatum* (American Podophyllum).
- It is a cytotoxic compound and serves as a precursor for the synthesis of important anticancer drugs like etoposide, teniposide, and etopophos.

Industrial Production

A. Source Plant

- Botanical names:
 - *Podophyllum hexandrum* Royle (Himalayan mayapple)
 - *Podophyllum peltatum* Linn. (American mayapple)
- Family: Berberidaceae
- Plant part used: Rhizomes and roots

B. Cultivation

- Grown in cool temperate regions (mainly Himalayas at altitudes of 2000–4000 meters).
- Requires shady areas, well-drained soil, and moderate rainfall.
- Plants are propagated through rhizome cuttings or seed germination.

C. Extraction Process

1. Collection & Drying:
 - The rhizomes and roots are collected in late summer, cleaned, and dried in shade.
2. Powdering:
 - Dried roots are powdered to increase the surface area.
3. Extraction:
 - Extracted with ethanol or methanol using Soxhlet extraction or percolation method.
4. Concentration:
 - The extract is concentrated under reduced pressure to remove the solvent.
5. Purification:

- Podophyllotoxin is purified by solvent partitioning (using chloroform or ether) and recrystallization from methanol or acetone.
6. Industrial yield:
- Approximately 3–5% of podophyllotoxin can be obtained from *P. hexandrum* rhizomes.

Alternative (Biotechnological) Production

- Plant tissue culture and hairy root cultures are now used to produce podophyllotoxin sustainably.
- Cell suspension cultures of *P. hexandrum* can yield high concentrations of podophyllotoxin with elicitors like methyl jasmonate.

Estimation of Podophyllotoxin

A. Spectrophotometric Method

- The extract is reacted with phosphoric acid reagent and measured at 290 nm using UV–Visible spectrophotometer.
- Calibration curve is prepared using standard podophyllotoxin.

B. High-Performance Liquid Chromatography (HPLC)

- Column: C₁₈ reverse-phase
- Mobile phase: Methanol : Water (70:30)
- Detection: UV detector at 290 nm
- Retention time: Approximately 5–7 minutes
- HPLC gives accurate quantitative estimation of podophyllotoxin in plant extracts and formulations.

C. Thin Layer Chromatography (TLC)

- Stationary phase: Silica gel G
- Mobile phase: Chloroform : Methanol (9:1)
- Detection: Under UV light (254 nm) or after spraying with sulfuric acid reagent (purple spot).

Utilization / Applications

A. Medicinal Uses

1. Antimitotic and Cytotoxic Agent:
 - Inhibits mitotic spindle formation by binding to tubulin.
2. Anticancer Precursor:
 - Used as a starting material in the semi-synthesis of anticancer drugs:
 - Etoposide
 - Teniposide
 - Etopophos
3. Antiviral and Antiwart Agent:
 - Used in Podophyllin resin for the topical treatment of genital warts, condyloma acuminata, and molluscum contagiosum.
4. Research Use:
 - Used as a model compound for studying microtubule assembly and cell division inhibition.

B. Industrial / Pharmaceutical Applications

- Podophyllin resin (containing ~25% podophyllotoxin) is used in dermatological preparations.
- Etoposide and teniposide derived from it are commercial chemotherapeutic agents used in:
 - Lung cancer
 - Testicular cancer
 - Lymphomas
 - Leukemias

C. Economic Importance

- High export demand due to anticancer drug synthesis.
- Overexploitation of *P. hexandrum* has led to its classification as an endangered species, hence biotechnological production is being emphasized.

Caffeine

- Caffeine is a purine alkaloid belonging to the xanthine group of compounds.
- It is a central nervous system (CNS) stimulant found naturally in various plants.
- It is widely used in pharmaceutical, food, and beverage industries due to its stimulant, diuretic, and bronchodilator properties.

Industrial Production of Caffeine

A. Natural Sources

- Botanical sources:
 - *Coffea arabica*, *Coffea robusta* (Coffee seeds)
 - *Camellia sinensis* (Tea leaves)
 - *Theobroma cacao* (Cocoa beans)
 - *Cola acuminata* (Kola nuts)
 - *Paullinia cupana* (Guarana)
- Family: Rubiaceae / Theaceae / Sterculiaceae (depending on the plant source)

B. Plant Part Used

- Tea leaves, coffee beans, cocoa beans, and kola nuts are used for extraction.

C. Extraction and Industrial Production Process

1. From Natural Sources

1. Raw material preparation:
 - Dried and powdered plant material (e.g., tea leaves or coffee beans) is used.
2. Defatting:
 - The powdered material is treated with petroleum ether or hexane to remove fats and waxes.
3. Extraction of caffeine:
 - The defatted material is extracted with hot water or chloroform, or by supercritical CO₂ extraction method.
 - Caffeine is soluble in hot water and chloroform.
4. Separation and purification:

- The aqueous extract is treated with basic lead acetate or calcium hydroxide to remove tannins.
- Caffeine is then extracted from the filtrate using chloroform.
- The solvent is evaporated to obtain crude caffeine, which is recrystallized from hot water or ethanol.

5. Drying and packaging:

- The purified caffeine crystals are dried under vacuum and packed in moisture-proof containers.

2. Synthetic Production (Industrial Scale)

- Chemical synthesis is used for large-scale, economical production.
- Common synthetic routes include:
 - From dimethylurea and malonic acid derivatives, using methylation and cyclization reactions.
- However, most industrial caffeine is now produced by decaffeination of coffee and tea (as a by-product).

Estimation of Caffeine

A. Gravimetric Method

- Involves extraction of caffeine from plant material using chloroform.
- After solvent evaporation, the weight of caffeine crystals gives its quantitative amount.

B. UV-Visible Spectrophotometric Method

- Principle: Caffeine absorbs strongly at $\lambda_{\text{max}} = 273 \text{ nm}$ in UV region.
- Procedure:
 - Extract caffeine in chloroform and dilute appropriately.
 - Measure absorbance at 273 nm against solvent blank.
 - Determine concentration using Beer-Lambert law and standard calibration curve.

C. High-Performance Liquid Chromatography (HPLC)

- Column: C₁₈ reverse-phase
- Mobile phase: Water : Methanol (80:20) or Acetonitrile : Water (30:70)
- Flow rate: 1 mL/min
- Detection: UV detector at 273 nm

- HPLC gives accurate quantification of caffeine in beverages and pharmaceuticals.

D. Thin Layer Chromatography (TLC)

- Stationary phase: Silica gel G
- Mobile phase: Chloroform : Acetone (9:1)
- Detection: Under UV light (254 nm); caffeine appears as a blue-violet spot.

Utilization of Caffeine

A. Medicinal / Pharmacological Uses

1. CNS Stimulant:
 - Increases alertness, reduces fatigue, and improves mental performance.
 - Used in headache and migraine formulations (with ergotamine or paracetamol).
2. Cardiac Stimulant:
 - Stimulates heart rate and increases contractility at moderate doses.
3. Diuretic:
 - Promotes urine formation by increasing renal blood flow.
4. Respiratory Stimulant:
 - Used in treatment of neonatal apnea (as caffeine citrate injection).

B. Industrial and Commercial Uses

1. Food and Beverages:
 - Used in tea, coffee, energy drinks, soft drinks, and colas as a flavoring and stimulant ingredient.
2. Pharmaceutical Industry:
 - Included in analgesic, antipyretic, and cold formulations (e.g., Anacin, Saridon).
3. Cosmetic Industry:

- Used in anti-cellulite creams, shampoos, and under-eye gels due to its vasoconstrictive and antioxidant properties.

Taxol (paclitaxel)

- Taxol (generic name: Paclitaxel) is a diterpenoid compound belonging to the taxane class of natural products.
- It is a potent anticancer (antineoplastic) agent originally isolated from the bark of the Pacific yew tree (*Taxus brevifolia*).
- Taxol works by stabilizing microtubules and inhibiting cell division (mitosis), leading to cell death in rapidly dividing cancer cells.

Industrial Production

A. Natural Source

- Botanical source: *Taxus brevifolia* (Pacific yew) and *Taxus baccata* (European yew).
- Family: Taxaceae
- Plant part used: Bark, needles, and leaves.

B. Problem with Natural Extraction

- The concentration of Taxol in bark is extremely low (~0.01–0.03%).
- Extraction from bark requires felling mature trees, making the process environmentally destructive and uneconomical.
- Hence, alternative methods have been developed for large-scale production.

C. Industrial Production Methods

1. Extraction from Natural Source

- Process:
 1. The powdered bark of *Taxus brevifolia* is extracted with organic solvents (e.g., methanol or ethanol).
 2. The extract is partitioned using solvents like chloroform or ethyl acetate.
 3. The crude extract is subjected to column chromatography using silica gel to purify Taxol.

4. Final purification is done by recrystallization from suitable solvents (e.g., methanol).
- Drawback: Not sustainable due to deforestation and low yield.

2. **Semi-Synthetic Production (Main Industrial Method)**

- The semi-synthetic method is the most widely used industrial process today.
- Starting material: 10-Deacetylbaccatin III (a natural precursor) isolated from leaves and needles of *Taxus baccata*.
- Steps:
 1. 10-Deacetylbaccatin III is extracted from *Taxus baccata* leaves.
 2. It undergoes chemical side-chain modification (esterification and acylation reactions).
 3. These chemical reactions convert the precursor into Paclitaxel (Taxol).
- Advantages:
 - Leaves can be harvested without cutting down trees.
 - Higher yield and environmentally friendly.

3. **Plant Cell Culture Technique**

- *Taxus* species cell suspension cultures are used for large-scale biotechnological production.
- The process involves:
 - Culturing *Taxus* cells in bioreactors using nutrient-rich media.
 - Addition of elicitors (like methyl jasmonate or fungal extracts) to enhance Taxol synthesis.
 - Extraction of Taxol from cultured cells using organic solvents.
- Advantages:
 - Sustainable, eco-friendly, and scalable for pharmaceutical industries.

4. Endophytic Fungi Production

- Some endophytic fungi (e.g., *Taxomyces andreanae*) associated with *Taxus* trees also produce Taxol.
- Fungal fermentation is being explored as a cost-effective industrial method for future large-scale production.

Estimation of Taxol

A. UV-Visible Spectrophotometry

- Principle: Taxol absorbs light at $\lambda_{\text{max}} = 230 \text{ nm}$ in methanol.
- Procedure:
 - Prepare methanolic extract of Taxol.
 - Measure absorbance at 230 nm.
 - Quantify using Beer-Lambert law and a standard calibration curve of Taxol.

B. High-Performance Liquid Chromatography (HPLC)

- Most accurate and preferred method for estimation.
- Column: C₁₈ reverse-phase.
- Mobile phase: Acetonitrile : Water (50:50).
- Flow rate: 1.0 mL/min.
- Detection wavelength: 230 nm (UV detector).
- Retention time: Around 10–12 minutes.
- Used for quantitative and purity analysis of Taxol in plant extracts and formulations.

C. Thin Layer Chromatography (TLC)

- Stationary phase: Silica gel G.
- Mobile phase: Chloroform : Methanol (9:1).
- Detection: UV light at 254 nm or spraying with sulfuric acid reagent (violet-blue spot).
- Used for qualitative identification.

Utilization / Applications

A. Medicinal Uses

1. Anticancer Agent:
 - Used in the treatment of several types of cancers, including:
 - Ovarian cancer
 - Breast cancer
 - Lung cancer
 - Kaposi's sarcoma (HIV-related)
 - Cervical and pancreatic cancers
2. Mechanism of Action:
 - Taxol binds to β -tubulin subunit of microtubules.
 - It stabilizes microtubules, preventing their depolymerization during mitosis.
 - This causes mitotic arrest, leading to apoptosis (programmed cell death) of cancer cells.
3. Other Actions:
 - Exhibits antiangiogenic (prevents new blood vessel formation) and immunomodulatory effects.

B. Industrial and Pharmaceutical Applications

1. Pharmaceutical Formulations:
 - Used in injectable forms such as Paclitaxel injection (Taxol®) and Nanoparticle Albumin-bound Paclitaxel (Abraxane®).
2. Nanotechnology Use:
 - Incorporated into liposomes, nanoparticles, and micelles to improve solubility and delivery.
3. Research Use:
 - Used in cell biology studies for understanding microtubule dynamics and cell cycle regulation.

Vincristine

- Vincristine is a vinca alkaloid, a group of indole–indoline alkaloids obtained from the Madagascar periwinkle plant (*Catharanthus roseus*).
- It is an important anticancer (antineoplastic) drug used in the treatment of various cancers.
- Chemically, vincristine and its related compound vinblastine are dimeric indole alkaloids derived from the condensation of two monomeric alkaloids — vindoline and catharanthine.
- Vincristine interferes with microtubule formation, thus preventing cell division (mitosis).

Industrial Production

A. Natural Source

- Biological source: *Catharanthus roseus* (also known as *Vinca rosea*)
- Family: Apocynaceae
- Plant part used: Leaves (major source of vincristine and vinblastine)

B. Cultivation

- *Catharanthus roseus* is cultivated in tropical and subtropical regions.
- Requires well-drained sandy soil, warm climate, and moderate rainfall.
- The plant can be propagated by seeds or stem cuttings.
- Leaves are harvested when the plant reaches maturity (about 6–8 months old).

C. Extraction and Isolation Process

1. Collection and Drying

- Leaves are collected, dried under shade, and powdered for extraction.

2. Extraction

- Powdered leaves are extracted with methanol or ethanol using Soxhlet extraction or percolation.
- The crude extract is concentrated under reduced pressure.

3. Acid-Base Extraction

- The concentrated extract is treated with dilute acid (H_2SO_4 or HCl) to form water-soluble alkaloid salts.
- The acidic solution is filtered and basified (pH ~9) using ammonia or sodium carbonate, liberating free alkaloids.
- The free alkaloids are extracted using organic solvents like chloroform or benzene.

4. Purification

- The extract is concentrated, and vincristine is separated from other alkaloids (like vinblastine) using:
 - Column chromatography (on alumina or silica gel)
 - Preparative HPLC

5. Industrial Scale Production

- Because the natural yield is very low (0.0002–0.0005% dry weight), large-scale production uses plant tissue culture and biotechnological methods:
 - Cell suspension cultures of *C. roseus* are grown in bioreactors.
 - Addition of elicitors (e.g., methyl jasmonate) enhances vincristine production.
 - Extracted from culture media using organic solvents and purified chromatographically.

D. Yield

- Yield of vincristine from natural leaf extraction: 0.002–0.005%.
- Biotechnological processes improve yield and reduce environmental impact.

Estimation of Vincristine

A. UV-Visible Spectrophotometric Method

- Principle: Vincristine shows strong absorbance in the UV range due to its indole chromophore.
- λ_{max} : 297 nm in methanol or ethanol.
- Procedure:
 1. Dissolve a known quantity of vincristine in methanol.
 2. Measure absorbance at 297 nm.
 3. Determine concentration using Beer-Lambert law and standard curve.

B. High-Performance Liquid Chromatography (HPLC)

- Most accurate and preferred method.
- Column: C₁₈ reverse-phase column
- Mobile phase: Methanol : Water (80:20) or Acetonitrile : Water (60:40)
- Flow rate: 1.0 mL/min
- Detection: UV detector at 297 nm
- Retention time: Approximately 8–10 minutes
- Used for quantitative estimation and quality control of vincristine in formulations.

C. Thin Layer Chromatography (TLC)

- Stationary phase: Silica gel G
- Mobile phase: Chloroform : Methanol : Ammonia (90:10:1)
- Detection: UV light at 254 nm or by spraying with Dragendorff's reagent (orange-brown spot).
- Used for qualitative identification.

Utilization / Applications

A. Medicinal Uses

1. Anticancer Agent:
 - Vincristine is used to treat:
 - Acute lymphoblastic leukemia (ALL)
 - Hodgkin's lymphoma
 - Non-Hodgkin's lymphoma
 - Wilms' tumor
 - Neuroblastoma
 - Rhabdomyosarcoma
2. Mechanism of Action:
 - Vincristine binds to tubulin proteins, preventing their polymerization into microtubules.
 - This inhibits mitotic spindle formation, leading to metaphase arrest and cell death.
3. Combination Chemotherapy:
 - Commonly used in combination regimens like:
 - CHOP (Cyclophosphamide, Doxorubicin, Vincristine, Prednisolone)
 - MOPP (Mechlorethamine, Oncovin [Vincristine], Procarbazine, Prednisone)

B. Industrial and Pharmaceutical Uses

1. Pharmaceutical Formulations:
 - Marketed as Vincristine sulfate injection (Oncovin[®], Vincasar[®]).
 - Available in lyophilized vials or solution form for intravenous use.
2. Research Applications:
 - Used as a reference standard in pharmacognostic and anticancer studies.
 - Useful in studying microtubule dynamics in cell biology.
3. Economic Importance:
 - High-value anticancer compound with significant export potential.

Vinblastine

- Vinblastine is a vinca alkaloid obtained from the plant *Catharanthus roseus* (commonly known as periwinkle or Madagascar periwinkle).
- It is a cytotoxic bisindole alkaloid with potent anticancer properties. Vinblastine acts by inhibiting microtubule formation in mitotic cells, preventing cell division.

Industrial Production

a) Source

- Biological source: *Catharanthus roseus* (Family: Apocynaceae)
- Parts used: Leaves and aerial parts

b) Biosynthetic Origin

- Vinblastine is formed by coupling two indole alkaloids:
 - Catharanthine (from tryptophan pathway)
 - Vindoline (from secologanin pathway)
- The coupling occurs through a peroxidase-catalyzed reaction in the plant to form Vinblastine and Vincristine.

c) Extraction and Isolation Process

1. Collection and Drying: Mature leaves of *Catharanthus roseus* are collected, dried, and powdered.
2. Extraction:
 - The powdered leaves are extracted with organic solvents such as methanol or ethanol.
 - The extract is concentrated and partitioned between acidic aqueous and organic layers (e.g., chloroform or dichloromethane).
3. Purification:
 - Alkaloids are precipitated from the acidic extract by basification (pH adjustment).
 - Further purification is carried out by chromatographic techniques like column chromatography or HPLC.
4. Isolation:
 - Vinblastine is separated from other vinca alkaloids by fractional crystallization or reversed-phase HPLC.

d) Industrial Methods

- Due to low natural yield (only about 0.0002–0.0005% of dry leaf weight), semi-synthetic production is preferred.
- Vinblastine is often semi-synthesized from vindoline and catharanthine, isolated separately from the plant.
- Biotechnology approaches like plant tissue culture, cell suspension culture, and hairy root culture are being developed to enhance alkaloid yield.

Estimation (Assay Methods)

a) Spectrophotometric Method

- Based on formation of a colored complex between vinblastine and reagents like bromocresol green in acidic medium.
- The absorbance is measured at $\lambda_{\text{max}} = 415 \text{ nm}$.

b) High-Performance Liquid Chromatography (HPLC)

- Most reliable and precise method.
- Mobile phase: Methanol : Water or Acetonitrile : Buffer (pH 3–4).
- Detection: UV detector at 254 nm.
- Used for quantitative estimation of vinblastine and related alkaloids in plant extracts or formulations.

c) Thin Layer Chromatography (TLC)

- Used for qualitative identification.
- R_f value helps confirm the presence of vinblastine.

Utilization / Therapeutic Uses

Vinblastine is a potent anticancer drug used mainly in chemotherapy.

Major Therapeutic Applications

1. Hodgkin's lymphoma
2. Non-Hodgkin's lymphoma
3. Testicular cancer
4. Breast cancer
5. Choriocarcinoma
6. Kaposi's sarcoma (associated with HIV/AIDS)

Mechanism of Action

- Vinblastine binds to tubulin, a structural protein in microtubules.
- Prevents polymerization of microtubules, blocking mitotic spindle formation.
- Leads to cell cycle arrest in metaphase, causing apoptosis (programmed cell death).

Dosage Form

- Administered as intravenous injection in combination chemotherapy regimens.

Industrial and Commercial Aspects

- Brand names: Velbe®, Cytoblastin®, Vinblastine Sulfate Injection.
- Manufacturers: Eli Lilly, Cipla, Teva, and others.
- Challenges:
 - Low yield from plant sources.
 - High cost of extraction and purification.
 - Need for biotechnological enhancement to ensure sustainability.
